# Loading and preprocessing the data

1. Load data.table and dplyr packages for data manipulation, and ggplot2 plus scales for plotting.

```
if (!require(data.table)) {install.packages("data.table"); library(data.table)}
if (!require(dplyr)) {install.packages("dplyr"); library(dplyr)}
if (!require(ggplot2)) {install.packages("ggplot2"); library(ggplot2)}
if (!require(scales)) {install.packages("scales"); library(scales)}
```

- 2. Download data file and extract the .zip file if not already present in data/directory
- 3. Read .csv file using data.table::fread wrapping the output using the %>% operator which pipes the output first into a data.table object, then a dplyr::tbl\_dt object.

Next we alter the loaded table using dplyr's mutate function

- 1. Convert date to integer-based IDate class from data.table package. Though not useful for this smaller data table, it can sort more quickly with very large data sets
- 2. Likewise, ITime an integer time format is calculated from the interval column.
- Interval <integer division> 100 gives the hours
- Interval <modulo> 100 gives the minutes
- 3. date, time is created as a data.table key, thereby accelerating any future access of the data.

Now "activity" looks like:

```
str(activity)
```

```
## Classes 'tbl_dt', 'tbl', 'data.table' and 'data.frame': 17568 obs. of 4 variables:
## $ steps : int NA ...
## $ date : IDate, format: "2012-10-01" "2012-10-01" ...
## $ interval: int 0 5 10 15 20 25 30 35 40 45 ...
## $ time :Class 'ITime' int [1:17568] 0 300 600 900 1200 1500 1800 2100 2400 2700 ...
## - attr(*, ".internal.selfref")=<externalptr>
## - attr(*, "sorted")= chr "date" "time"
```

### head(activity)

```
##
                 date interval
                                   time
     steps
## 1
       NA 2012-10-01
                             0 00:00:00
## 2
        NA 2012-10-01
                             5 00:05:00
## 3
       NA 2012-10-01
                            10 00:10:00
## 4
       NA 2012-10-01
                            15 00:15:00
## 5
       NA 2012-10-01
                            20 00:20:00
## 6
       NA 2012-10-01
                            25 00:25:00
```

## What is mean total number of steps taken per day?

To summarize the data into total steps taken per day, we could drop all time intervals that include an NA

```
activity %>% filter(!is.na(steps)) %% group_by(date) %>% summarise(sum(steps))
```

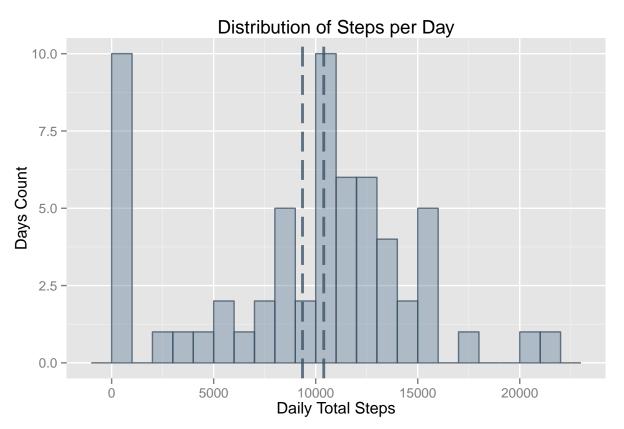

However, that completely drops some dates, such as 2012-10-01 and 2012-11-01, which have no valid measurements. At this point in the assignment, rather than imputing missing values, we are trying to show the limitations of ignoring the NAs. One way to do this is to read the NAs as zeros which simply do not add to the sum of steps.

```
activity <- activity %>%
   mutate(stepsZeroNAs = ifelse(test = is.na(steps), yes = 0, no = steps))
#stepsZeroNAs column = Steps with ZERO in place of NAs

stepCounts <- activity %>%
   group_by(date) %>%
   summarise(stepsZeroNAs=sum(stepsZeroNAs))
```

Now, lets build a histogram of the data using ggplot2

```
# color
tempHue <- 0.58
ColA.light <- hsv(h = tempHue, s = 0.4, v = 0.6, alpha = 0.4)
ColA.dark \leftarrow hsv(h = tempHue, s = 0.4, v = 0.4, alpha = 0.8)
# mean and median
meanstepsZeroNAs <- mean(stepCounts$stepsZeroNAs)</pre>
medianstepsZeroNAs <- median(stepCounts$stepsZeroNAs)</pre>
dailySteps <-
  # choose data
  ggplot(data = stepCounts) +
  # aesthetics, one series => histogram
  aes(x = stepsZeroNAs) +
  # geometric details of histogram, including coloring
  geom_histogram(fill=ColA.light, colour=ColA.dark, binwidth = 1000) +
  # annotate mean and median values
  geom_vline(xintercept=meanstepsZeroNAs, colour=ColA.dark, size=1.0, linetype="longdash") +
  geom_vline(xintercept=medianstepsZeroNAs, colour=ColA.dark, size=1.0, linetype="longdash") +
  # Add labels
  labs(
    title = "Distribution of Steps per Day",
    x = "Daily Total Steps", y = "Days Count")
# execute the plot
dailySteps
```

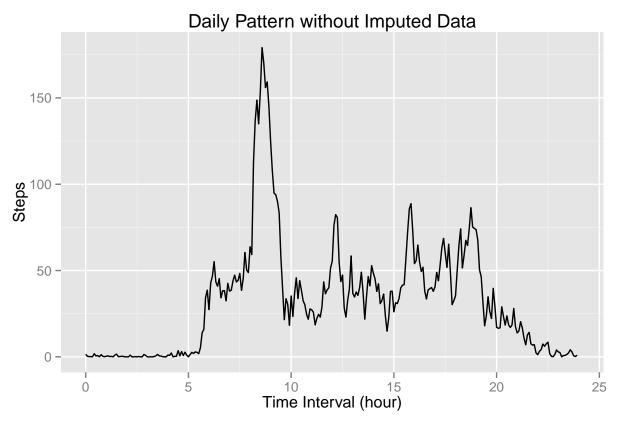

9354 is the mean number of steps taken in a day, as calculated from data where NA is treated like no steps in that time period

10395 is the median, using the same data

# What is the average daily activity pattern?

Calculate typical daily pattern, with NAs ignored and with NAs treated as zero.

Then plot the data

From this calculation, we can note that typically, the most active 5-minute interval during the day starts at:

```
dailyPattern[stepsZeroNAs==max(dailyPattern$stepsZeroNAs), time]
```

```
## [1] "08:35:00"
```

## Imputing missing values

The original data set contained 2304 NAs, out of a total 17568 observations.

The typical number of steps at each time interval during the day was calculated in the previous section

This table can be used to impute typical values for the NAs in the original data set. It covers all time intervals during the day covered by the earlier method of turing NAs into zeroes:

```
length(unique(dailyPattern$stepsTypical)) == length(unique(dailyPattern$stepsZeroNAs))
## [1] TRUE
```

And, it contains no NAs:

```
sum(is.na(length(unique(dailyPattern$stepsTypical))))
```

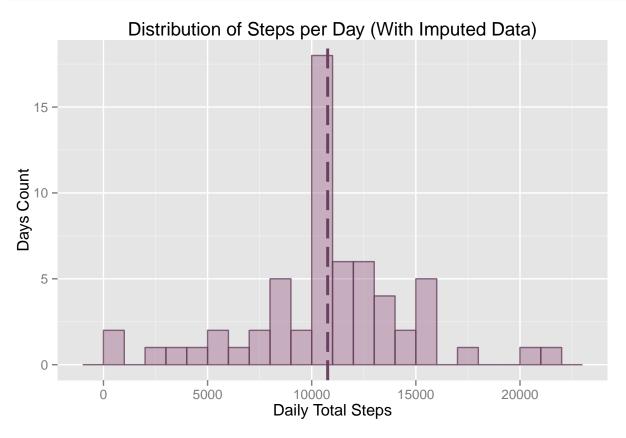

```
## [1] 0
```

This table can be used to create a new column in the original data set that imputes missing values from the typical daily pattern in cases there were NA values previously.

```
activity <- activity %>%
   mutate(stepsTypical = ifelse(
     test = is.na(steps),
     yes = dailyPattern[time==time, stepsTypical],
     no = steps))
```

These new data can be plotted like before:

```
dailySteps.Imputed <-
  # choose data
  ggplot(data = stepCounts) +
  # aesthetics, one series => histogram
  aes(x = stepsImputed) +
  # geometric details of histogram, including coloring
  geom_histogram(fill=ColB.light, colour=ColB.dark, binwidth = 1000) +
  # annotate mean and median values
  geom_vline(xintercept=meanstepsImputed, colour=ColB.dark, size=1.0, linetype="longdash") +
  geom_vline(xintercept=medianstepsImputed, colour=ColB.dark, size=1.0, linetype="longdash") +
  # Add labels
  labs(
    title = "Distribution of Steps per Day (With Imputed Data)",
    x = "Daily Total Steps", y = "Days Count")
# execute the plot
dailySteps.Imputed
```

Are there differences in activity patterns between weekdays and weekends?

```
activity <- activity %>%
mutate(weekday= ifelse(
   weekdays(date) %in% c("Saturday", "Sunday"),
   "Weekend",
   "Weekday"))
```

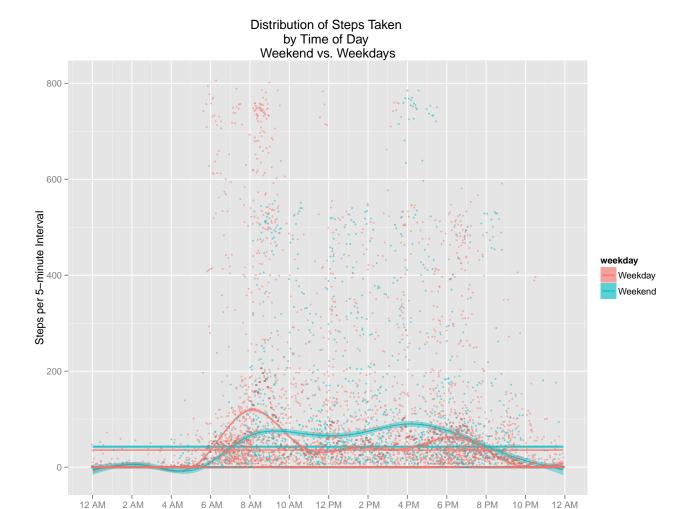

```
dailyPattern.split <- activity %>%
    group_by(time, weekday) %>%
    summarise(time, steps=mean(stepsTypical))

ggplot(data = dailyPattern.split, aes(x = as.POSIXct(time), y = steps, color = weekday)) +
    scale_x_datetime(breaks = date_breaks("2 hour"), labels = date_format("%1 %p")) +
    # See documentation for `scales` package to understand `scale_x_datetime`,
    # `date_breaks` and `date_format` transformation of times along x-axis
    facet_grid(weekday ~ .) + geom_line() +
    labs(title = sprintf(
        "Distribution of Steps Taken \nby Time of Day \nWeekend vs. Weekdays"),
        x = "Interval", y = "Steps per 5-minute Interval")
```

#### Distribution of Steps Taken by Time of Day Weekend vs. Weekdays 200 Steps per 5-minute Interval 50 weekday Weekday Weekend 100 -50 Ω 2 AM 4 AM 6 AM 8 AM 10 AM 12 PM 10 PM 12 AM 12 AM 8 PM

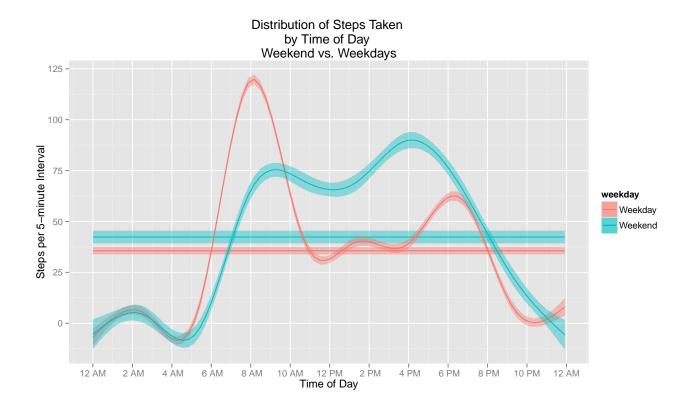

And, just for fun here is an additional plot of the data

```
ggplot(data = activity, aes(x = as.POSIXct(time), y = stepsTypical, colour = weekday, fill = weekday))
scale_x_datetime(breaks = date_breaks("2 hour"), labels = date_format("%l %p")) +
stat_smooth(method = "gam") + geom_smooth(level = 0.8) +
geom_point(alpha=0.5, size=1, position = "jitter") +
labs(title = sprintf(
    "Distribution of Steps Taken \nby Time of Day \nWeekend vs. Weekdays"),
    x = "Time of Day", y = "Steps per 5-minute Interval")
```

And, zooming in on the smoothed data

Time of Day

# Appendix B: Notes on Selected R Packages

## dplyr 0.4.1

- summary https://github.com/hadley/dplyr/blob/v0.4.1/README.md
- news https://github.com/hadley/dplyr/blob/v0.4.1/NEWS.md

**Dplyr** by Hadley Wickam builds upon the earlier plyr package for data manipulation and shaping for analysis. Execution speed approaches that of data.table with syntax patterns that are arguabley more consistent with other R packages. Additionally, dplyr can serve as a wrapper around data.table objects.

Note that dplyr also automatically imports magrittr

- mutate() This function takes a data frame or data table in dplyr and adds columns with values as specified. It leaves existing columns in place regardless of whether they are specified. This is in contrast to transmute() which drops any existing columns that are not specified to be output.
- group\_by() & summarise() Replicate functinality found in base R functions like aggregate(), \*apply(), by() and subset()

#### magrittr 1.5

- overview https://github.com/smbache/magrittr/blob/v.1.5/README.md
- vignettes http://cran.r-project.org/web/packages/magrittr/vignettes/magrittr.html

Magrittr supplies a "forward pipe" operator %>% which is useful for composing functions. The following two expressions:

```
order(upper(c("c", "b", "a")))
is equivalent to:
c("c", "b", "a") %>%
     upper() %>%
     order()
```

#### scales 0.2.4

Required for ggplot2's scale\_x\_dateime http://docs.ggplot2.org/current/scale\_datetime.html

## tidyr 0.2.0

- summary https://github.com/hadley/tidyr/blob/v0.2.0/README.md
- source https://github.com/hadley/tidyr
- CRAN http://cran.r-project.org/web/packages/tidyr/index.html

**Tidyr** can be used to shape data. In database theory, such operation are equivalent to changing between different normal forms. Tidyr focuses around gather(), which makes wide tables tall, and spread() which makes tall tables wide.
